The effect of some nutritional substances on the increase of the resistance of guinea pigs to aniline poisoning. A. I. Shtenberg, Yu. I. Shillinger, and L. P. Naumova (Inst. Nutrition Acad. Med. Sci. U.S.S.R., Moscow). *Voprosy Pitaniya* 13, No. 1, 21-7(1954).—Five different diets have been used to study the rates and ways of recovery of the guinea pigs from aniline (I) poisoning resulting from subcutaneous injection of 80 mg. I in sunflower oil/100 g. body wt. (toxic dose). The results indicate that ascorbic acid, nicotinic acid, lecithin, and Ca-enriched cottage cheese added to a normal diet increased the resistance of the guinea pigs against I poisoning as well as increased the rate of the detoxication of the organism. This was shown by an increase of the blood-regenerating activity of the organism (increased hemoglobin and erythrocyte count which were decreased by the I injection), by normalization of the peroxidase activity (lowered by I) and the sugar level of blood (raised by I up to 120 mg. % as compared with 94-103 mg. % for the control), and by the urine excretion of p-aminophenol (II) and phenol (taking place usually within 24 hrs. after the I injection) (in all 30 control animals no II was found in the urine). All animals showed morphological changes of the internal organs (brain, spleen enlarged and darkened), blood vessels, and nervous and reticulo-endothelial systems) as the result of the I injection.

Title : Concerning the etiology of so-called Dzhalangarsk Encephalitis

Periodical : Vop. pit., 27-31, May/Jun 1955

Abstract : Starting in 1942, cases of neuroinfection were recorded in the Uzbek SSR and were called Dzhalangarsk Encephalitis because of the clinical and pathomorphological picture they presented. A filterable virus was extracted from the organs of victims. However, attention was drawn to a patient who ate some uncleaned wheat taken from under a combine in 1950, and had the same symptoms. This led to the belief that this illness might be caused by a toxicological factor. The toxic element was subsequently found to be contained in the seed of trichodesma incanum, collected along with the wheat. The seed was found to yield an alkaloid which was toxic. In the present work, experiments were conducted on rats, mice, rabbits, and guinea pigs to determine the effects of eating the seed, and the alkaloid (dissolved in 0.1 N HCl). Depending on the concentration and method of administration (seed or alkaloid) the same symptoms appeared sooner or later, i.e. pathologic changes in the central

Card 2/2

nervous system, involuntary urination, and hemorrhaging in the lungs and small intestine. Authors feel that the name Dzhalangarsk Encephalitis is not correct and should be changed to Dzhalangarsk toxicosis. Fourteen references (all USSR; 13 since 1940).

TITLE: Toxicological study of combined effects of pesticides

SOURCE: Voprosy pitaniya, v. 24, no. 4, 1965, 3-9

TOPIC TAGS: toxicology, pesticide, poison effect, combinatorial analysis, experiment animal

ABSTRACT: Based on studies at the author's institute, recommendations are made which complement those issued earlier for single pesticides. The need for animal studies of acute, subacute and chronic toxicity of various ratios of combinations is stressed. The effect of pesticide combinations may be summary, synergistic or antagonistic. Combinations of LD₅₀ of each component are studied to determine to which of the 3 types the mixture belongs. Toxicity changes upon successive introduction of the components must be considered. The technique of animal tests is briefly described. Subacute tests help determine toxicodynamics and threshold toxic doses. Chronic tests should be conducted by add-

Card 1/2

TITLE: Fundamental principles underlying the study of toxicity of food additives

SOURCE: AMN SSSR. Vestnik, no. 10, 1966, 48-56

TOPIC TAGS: toxicology, commercial food product, hygiene, contaminant, Food
TECHNOLOGY

ABSTRACT: The importance of carefully planned and performed experiments in the evaluation of the toxicity of food additives is stressed. Primarily, the chemical composition of the additive and its purity must be known. Results obtained with pure and commercial products should be compared for proper evaluation of the effects of the substance, as should results of experiments on different animal species. These tests should cover long periods of time so that cumulative effects, if any, will appear.

TITLE: A device for fastening an element inside a shell in a gas stream. Class 47, No. 179143

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 4, 1966, 124

TOPIC TAGS: gas flow, aerodynamic drag

ABSTRACT: This Author's Certificate introduces a device containing braces for fastening an element inside a shell in a gas stream. Hydraulic drag is reduced and the reliability of the fastening is improved by installing the braces at an angle to the axis of the shell and by using ball-and-socket hinges for fastening the braces to the inside surface of the shell and to the element.

<p>The passage of vanadium from its oxides into cast iron depending on the temperature, basicity and amount of slag. V. V. Mikhailov and S. V. Shtengel'meyer. <i>Ural. Izv.</i> 1930, No. 7, 9-13; <i>Khim. Refrat. Zhur.</i> 1930, No. 12, 87.—V-free cast iron was treated in C crucibles with slags produced from SiO_2, Al_2O_3, CaO, MgO and V_2O_5. The acid slag m. 1200°, the basic slag m. 1300°. Below 800° V_2O_5 and V_2O_4 are reduced readily to V_2O_3 by means of CO. V_2O_3 is reduced to V_2O_2 by solid C only at 1200°. Free V_2O_3 in the fused slag is reduced at 1300° by C to metallic V, which passes into cast iron. Increase of the temp. of the blast facilitates rapid and complete transfer of V from the slag to the metal. To decrease the losses of V in the slag it is recommended to smelt V ores low in FeO_3 with basic slags, at higher temps. of the hearth of the blast furnace. Low ratio of slag to cast iron decreases losses of V.</p> <p>W. R. TITLE: Viscosity of fluxes used for electroslag melting and preheating

SOURCE: Avtomaticheskaya svarka, no. 11, 1965, 28-30

TOPIC TAGS: electroslag melting, calcium fluoride, calcium oxide, magnesium oxide, fluid viscosity

ABSTRACT: The authors study viscosity as a function of temperature in 11 calcium fluoride fluxes recommended for electroslag melting and preheating. It is found that the viscosity of the calcium fluoride melt is low (0.2-0.3 poise) when heated above the liquidus curve ($\Delta t = 40^{\circ}\text{C}$). Components which lower the crystallization temperature of the melt also reduce the viscosity due to an increase in superheating above the liquidus curve. Additives which raise the crystallization temperature increase the viscosity. Examples of impurities which reduce the viscosity are sodium fluoride and cryolite, while calcium oxide and magnesium oxide increase the viscosity by raising the crystallization temperature. Calcium fluoride fluxes containing magnesium

TITLE: New electromagnetic vibrational viscosimeter

SOURCE: AN SSSR. Institut metallurgii. Eksperimental'naya tekhnika i metody vysokotemperaturnykh izmereniy (Experimental techniques and methods of high temperature measurement). Moscow, Izd-vo Nauka, 1966, 46-51

TOPIC TAGS: viscosimeter, fluid viscosity, fluid viscosity measurement, slag

ABSTRACT: An electromagnetic vibrational viscosimeter for determining viscosity of melts was developed. The new device is an improved version of the viscosimeter invented by G. I. Leskov and G. D. Shevchenko (Elektricheskiy vibratsionnyy viskozimetr. Zavodskaya laboratoriya, 1956, No. 4, 492). The main improvements are: increased sensitivity, smaller specimen size, and continuous viscosity recording. A schematic of the instrument is presented. The instrument was used to determine the viscosity of Marten open-hearth slag and blast furnace slag. The results are shown graphically (see Fig. 1). It is concluded that, in the case of undisturbed homogeneous and noncorrosive slags, the viscosimeter is capable of yielding 3 to 4 complete viscosity-temperature curves during the period of one working day, at a
